Role of Microfinance for
Safety Nets of the Poor**

ZEF – Discussion Papers on Development Policy
Bonn, October 1999

The **CENTER FOR DEVELOPMENT RESEARCH (ZEF)** was established in 1997 as an international, interdisciplinary research institute at the University of Bonn. Research and teaching at ZEF aims to contribute to resolving political, economic and ecological development problems. ZEF closely cooperates with national and international partners in research and development organizations. For information, see: <http://www.zef.de>.

ZEF – DISCUSSION PAPERS ON DEVELOPMENT POLICY are intended to stimulate discussion among researchers, practitioners and policy makers on current and emerging development issues. Each paper has been exposed to an internal discussion within the Center for Development Research (ZEF) and an external review. The papers mostly reflect work in progress.

The research for this paper was conducted in early 1999 when Prof. Zeller was a research fellow at the International Food Policy Research Institute (IFPRI), Washington, D.C. Financial support by the German Ministry of Development and Economic Cooperation (BMZ) is gratefully acknowledged. Prof. Zeller thanks Manohar Sharma, Joachim von Braun and participants of a seminar held at the Center for Development Research for their comments.

Abstract

Many of the poor borrow, more save, and most of them demand insurance products or related substitutes. However, most of these financial products, especially those catering towards the need for consumption stabilization are only offered by the informal market. Microfinance Institutions (MFIs) that wish to increase their relevance for the poor are well advised to innovate with financial services for income and consumption smoothing. Public action can further promote innovations by supporting pilot projects and related action research. Evaluations of MFIs that receive financial support by government or donors so as to make a contribution to the alleviation of poverty ought to include checks on whether the MFI provides financial products for income and consumption smoothing, such as precautionary savings services, emergency credit, insurance services, or implicit insurance substitutes. Such checks can be undertaken at low cost by simply looking at the terms of the financial products currently offered, and they can identify other poverty-oriented product innovations that can be easily implemented and can in many circumstances increase the business volume and profitability of the MFI.

Kurzfassung

Ein hoher Anteil der Armen nimmt Kredite auf, ein größerer Anteil spart, und die meisten fragen Versicherungsprodukte oder entsprechende Substituten nach. Allerdings sind die meisten finanziellen Dienstleistungen, besonders jene, die der Konsumstabilisierung dienen, nur auf informellen Märkten für die Armen erhältlich. Mikrofinanzinstitutionen (MFI), die beabsichtigen, ihre Bedeutung für die Armen zu erhöhen, wären gut beraten, neue finanzielle Produkte einzuführen, die zur Stabilisierung des Konsums beitragen und damit eine gewisse Absicherung gegenüber Produktions- und Konsumrisiken ermöglichen. Öffentliche Maßnahmen können solche Produktinnovationen durch die Unterstützung von Pilotprojekten und begleitender Aktionsforschung zusätzlich fördern. Die Evaluierung von Mikrofinanzinstitutionen, die öffentliche Gelder mit dem Ziel der Armutsbekämpfung erhalten, sollte prüfen, ob die von den MFIs angebotenen finanziellen Dienstleistungen zur Einkommens- und Konsumstabilisierung beitragen. Zu solchen Produkten gehören beispielsweise Produkte zum kurzfristigen Vorsorgesparen, Konsumkredite, und eine Reihe von Versicherungsprodukten. Solche Tests können mit geringen Kosten durchgeführt werden, da lediglich die Konditionen der bestehenden Palette der Finanzprodukte einer MFI auf ihre Eignung hinsichtlich der Einkommens- und Konsumstabilisierung zu prüfen sind. Es erscheint möglich, daß MFIs armutsorientierte Produktinnovationen zum Teil ohne großen Kostenaufwand einführen können, um damit nicht nur ihre Relevanz für ärmere Kundenkreise, sondern auch ihre Rentabilität zu erhöhen.

1 Financial Services, Income, and Consumption Smoothing

During the 1990s, governments, donors, private investors, and foundations have increasingly funded microfinance institutions (MFIs) that offer financial services to poor people. While there have been success stories, numerous failures have not made the headlines. The Consultative Group to Assist the Poorest (CGAP) estimates (Murdoch 1998, 26) that only 3 to 5 percent of MFIs worldwide are financially sustainable, that is, they do not depend on funds provided on concessional terms for the operation and expansion of the MFI. Another 7 to 10 percent are expected to become financially sustainable within 10 years. The other 90 percent of MFIs will either close or continue to require subsidies.

Two major schools of thoughts contribute to, nurture, and influence this movement. The first one may be termed the poverty lending approach and the second one the financial systems approach (Gulli 1998). The poverty lending approach can be associated with the spirit of the declaration of the Microcredit Summit that was held in Washington, D.C. in February 1997. During the summit, the role of microcredit for poor entrepreneurs, in particular women, for alleviating poverty was emphasized. The summit's participants called for increasing the number of households having access to microcredit from less than 10 million households in 1997 to 100 million households by 2005. The proponents of this school claim that microcredit can alleviate poverty. For that reason, subsidies for institutional innovation and expansion are justified. The second school focuses on sustainably providing financial services to low-income clientele. Proponents of this school argue that there is no justification for subsidies because future outreach critically hinges on achieving financial sustainability of the MFI.

Both schools have pitfalls and strengths, and combining their strengths in a more balanced view may eventually improve the implementation of policies and projects. Two of the pitfalls of the first school appear to be its overarching emphasis on credit rather than on savings, and its implicit assumption that spending donor funds and tax revenues on microcredit yields higher social benefit-cost ratios than any other alternative policy interventions, at least until 100 million households have been reached. In the IFPRI country study samples, in roughly half of the survey households at least one adult household member borrowed during the recall period of one to two years. Yet, almost all households were found to save (at least seasonally) during this period (Zeller and Sharma 1998). It is fair to say that all poor households enter into various forms of informal self-insurance or co-insurance arrangements. Moreover, regarding the social benefits argument, not one research study to my knowledge has so far measured the social benefits and social costs of public support to microcredit institutions. IFPRI's own empirical studies also fell short of that ambitious objective, limiting the analysis to measuring the private benefits of credit access for households. In four out of five country studies, credit access had

significant and sizable benefits for income and household food security (Zeller and Sharma 1998). The major difficulty of moving toward a full cost-benefit analysis of microfinance is that microcredit is not a single service that can be seen in a vacuum by applying a *ceteris paribus*-type of analysis, but its social return must be evaluated in conjunction with the variation of other complementary services provided or supported by the state, such as agricultural research, infrastructure, and investments in human capital and social services. Indeed, a number of studies indicate that the household-level returns to credit access (see, for example, the review by Sharma and Schrieder 1998) as well as loan repayment (Zeller 1998) are higher if access to input markets is improved. However, if access to financial markets is improved, for example through greater competition of microfinance institutions, Sharma and Zeller (1997) and Wenner (1995) find that delinquency rates increase as households have more or better alternatives for borrowing and are less likely to value any specific MFI. A satisfactory measure of the potential synergies among and trade-offs between competing policy instruments imposes steep requirements on data, mainly because of the need to correct for selection biases in placement of microfinance and complementary programs over space and time as well as for household's and individuals' participation in such programs. Moreover, the fungibility of financial resources within the household leads to significant problems of evaluation that have already been pointed out by von Pischke and Adams (1980). An adequate treatment of these three main problems of impact assessment requires large, carefully stratified panel data sets.

The second school seems to not appreciate the argument of welfare economists that MFIs are economically sustainable if the social benefits they generate outweigh their social costs.¹ In other words, when an MFI is economically sustainable, the state can subsidize the MFI up to the amount of the difference between social benefits and social costs of the MFI, and thereby eventually make the MFI financially sustainable. Such a win-win situation does not only occur for some of the flagships of the poverty lending approach, such as the Association for Social Advancement (ASA), the Bangladesh Rural Advancement Committee (BRAC), and the Grameen Bank in Bangladesh, but most likely also for many other public investments in MFIs in other countries, too.

A general criticism that applies to both schools is that they hardly mention the role of microfinance for household risk coping. They mainly emphasize the role of credit in productive investment and income generation in farm or nonfarm microenterprises and the role of savings for capital mobilization and long-term growth objectives. While saving was recognized as the forgotten half of finance in the 1980s, insurance can be termed its forgotten third during the 1990s (Zeller et al. 1997).

¹ See Zeller et al. 1997 on the definition of the term of economic sustainability versus financial sustainability of an institution.

Many households borrow, more save, and all insure. Poor, food-insecure households in developing countries seek to avoid the risk of falling below a minimum level of consumption of food and other basic goods that would threaten their livelihood or even survival. In general, two stages of risk coping can be differentiated. These are termed income smoothing and consumption smoothing: According to Murdoch (1995).

First, households can smooth income; this is most often achieved by making conservative production or employment choices and diversifying economic activities. In this way, households take steps to protect themselves from adverse income shocks before they occur. Second, households can smooth consumption by borrowing and saving, adjusting labor supply, and employing formal and informal insurance arrangements. These mechanisms take force after shocks occur and help insulate consumption patterns from income variability.

This paper explores the role of microfinance for income and consumption smoothing. In a nutshell, improved access to financial services can have two principal effects on household outcomes. First, it can raise the expected value of income and therefore of consumption and future investment and asset accumulation. This is the traditional and often sole argument for provision of services by MFIs. Second, it can decrease the variances of income and consumption. It is the second effect that is relevant for this paper. For the food-insecure poor, it is particularly important to reduce the downside risk of falling below minimum levels of disposable income for consumption of food and other basic needs. Therefore, the poor tend to value relatively more financial services that address the risk-coping motive, while the wealthy can afford to demand financial services that generate income and therefore accumulate assets. For example, while the rich and well-cushioned in developed countries buy stocks, the middle- and lower-income families prefer to hold more certificates of deposit, and the poor keep their money in a checking account or under the pillow. Similar behavior, albeit using different financial products, including a myriad of informal financial substitutes, can be observed among the wealthy and poor in developing countries.

This paper seeks to assess the role of microfinance for income and consumption smoothing by the poor. The principal policy implication of this paper is that the role of microfinance for risk-coping mechanisms is not well recognized, and therefore underutilized in policy and microfinance practice. While it is admittedly more difficult to offer savings and insurance services than credit, recent product innovations by a few MFIs suggest that there is room for better exploiting this potential. In the following sections, a conceptual framework is developed that distinguishes between credit, savings, and insurance services and identifies two principal pathways through which access to financial services can enhance income and smooth consumption. How the demand for these services is expected to change as the level of poverty and risk exposure of the household or individual increases is discussed. In the third section, the types of risks faced by households and potential areas for product innovation by the microfinance sector to address these risks are presented. The fourth section discusses the potential and limits of microfinance services in assisting households to cope with adverse

Towards Enhancing the Role of Microfinance for Safety Nets of the Poor

shocks. This section also provides a nonexhaustive list of examples of innovations already implemented by selected MFIs, which seeks to address the demand for financial services for smoothing income consumption. The paper concludes with policy recommendations.

2 The Role of Microfinance for Smoothing Income and Consumption: A Conceptual Framework

Figure 1 distinguishes two principal pathways through which access to financial services can increase and smooth income and consumption by households and their individual members. These pathways provide a framework for identifying institutional arrangements that address the poor's diverse demand for savings, credit, and insurance services, for evaluating them, and for comparing their costs and benefits with alternative policy measures aimed at alleviation of poverty and social protection. The process through which access to financial services influences income generation and consumption smoothing and the accumulation of physical, human, and social capital in future periods is depicted through the linkage of boxes. Each of the boxes indicates a subcomponent in the overall process. Time scripts are not shown, but the process is perceived as dynamic.

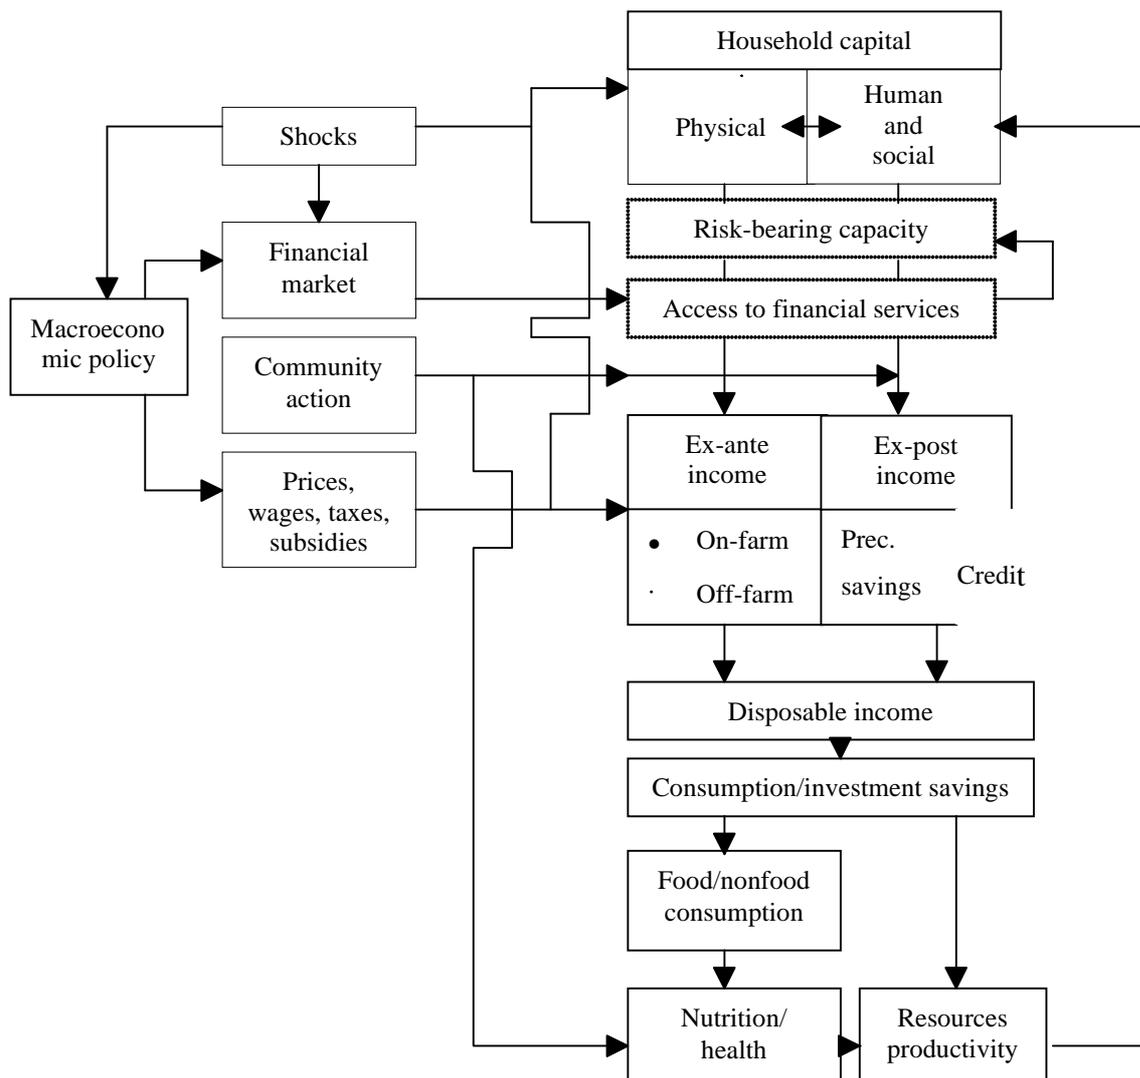

Access to financial services, that is, savings, credit, and insurance, is influenced by macroeconomic and financial sector policy and the specific policies and programs related to the promotion of MFIs catering to the poor. Weather, market, and other shocks influence the financial market and its institutions and trigger informal community action of self-help and informal credit and savings mechanisms. Shocks also influence the demand for financial services by households, either before or after the shock has occurred. The *ex ante* uncertainty about shocks induces households to hold reserves of monetary or physical capital and to preserve or increase their credit lines with formal or informal lenders by honoring past contracts or by providing gifts or loans to prospective future lenders.

Apart from policy action and district- and community-level characteristics that determine the formation of formal and informal financial institutions and therefore the supply side, the household's access to financial services is also influenced by its physical, human, and social capital.² Physical and social capital can serve as loan collateral. All three forms of capital determine the repayment capacity and therefore the creditworthiness of households or individuals.³ Moreover, households owning more of these three forms of capital have a higher capacity to bear risks. As pointed out by Eswaran and Kotwal (1990), access to credit can further increase the risk-bearing capacity (indicated by the feed-back arrow in Figure 1).

² For the impact of social capital on credit access, see, for example, Zeller, Diagne, and Mataya 1997; and Grootaert 1998.

³ The remainder of this section refers to households, although the framework is equally applicable to individuals if intrahousehold decisionmaking and asset allocation were added.

Figure 1: Access to financial services and its effects on income and consumption smoothing

Disposable income that is available for future consumption and investment consists of two components. The first component is the planned, ex-ante (or permanent) income that a household anticipates to earn through the use of its human, physical, and social capital. For example, human capital may allow the adoption and efficient use of more sophisticated technologies. Physical capital, such as land or production durables, helps to exploit economies of scale. Social capital (for example, membership in a producer and marketing cooperative) may result in higher household-level product prices, lower input prices, or more efficient production processes through mutual learning. All three types of financial services can in principal be used to enhance these forms of capital, and thereby increase the expected value or reduce the variance of ex-ante income. First, credit can increase the capital base of the household or make it more resilient against shocks. Second, savings accumulated in prior periods can be divested and used for the acquisition of any of the three types of capital needed for the income-generation process. Third, the household can enter into insurance contracts and undertake measures of self-protection

to safeguard itself against risks. While formal insurance services are usually not accessible by the urban and rural poor in developing countries, the poor seek to insure ex-ante by entering into personalized or group-based coinsurance strategies with the extended family and with friends who provide private transfers, in form of loans or gifts, when in need (Udry 1990; Cox and Jimenez 1992; Jacoby and Skoufias 1998) and by entering into bonded patron-client relationships (Bardhan 1984). The explicit or implicit risk premium paid by the household lowers the level of the ex-ante income, but also reduces its variance and in particular its downside risk. Further measures for smoothing income include the informal measures of self-protection—for example, the use of risk-reducing inputs or the diversification into different nonfarm, on-farm, and wage-earning activities that exhibit low covariance of returns. While these measures can again be effective in smoothing income, they can be very costly to the household and potentially also to society at large.

The second component of disposable income is generated ex-post by the household, that is after the income from farm and non-farm enterprises as well as from wage labor has been realized. If the ex-ante income turns out to be lower than the minimum level of disposable income required to satisfy the needs for food and other basic necessities, households engage in ex-post activities to generate additional disposable income. Again, these activities can in principal employ all three types of financial services. First, credit for consumption is demanded or production credit is diverted to consumption.⁴ Second, sale of assets (liquidation of previous savings) occurs. And, third, insurance claims are voiced, either by calling for gifts and remittances from the informal social network and from formal relief institutions, or if available, from formal insurers, such as social security schemes or crop or livestock insurance schemes.

In summary, the two pathways depicted in Figure 1 are:

Pathway 1 feeding into ex-ante income: via access to and use of credit and savings services to enhance the capital base for future income generation and via the use of insurance services (or of insurance substitutes) for smoothing ex-ante anticipated income,

Pathway 2 feeding into ex-post income: via access to and use of ex-post (consumption) credit, divestment of (precautionary) savings, and insurance claims.

⁴ It is important to note that production and consumption of a household that employs family labor in its enterprises and produces home-consumed goods are not separable. Because of this, the distinction between production and consumption is blurred. For example, consumption of food and other nonfood inputs into nutrition maintain productivity of family labor, the most important production factor of the poor, particularly the ultrapoor. This is well expressed by Dasgupta (1993): “At low levels of nutrition and health care, increases in current consumption improve future labor productivity: if nothing else, morbidity is reduced. . . . At the margin, consumption of basic needs amounts to investment. One may even go further and argue that consumption and investment at the margin are, over time, synergistic up to a point” (Dasgupta 1993, 247).

Thus, pathway 1 describes income smoothing, and includes all possible ex-ante measures taken by the household to increase income and to smooth future income. Murdoch (1995) points out that smoothing income can come at a significant cost, and that poor households, because of their higher exposure to risks and their lower risk-bearing capacity, incur relatively higher costs of forgone expected income for achieving smoother ex-ante income patterns. Binswanger and Rosenzweig (1993), cited in Murdoch 1995, measure the cost of income smoothing for the wealthy and the poor in the ICRISAT panel data set. Murdoch (1995, 109) discusses this study:

They estimate a production function that provides a measure of impact of riskiness (as dictated largely by the timing of rainfall) on input choice. As the environment becomes more risky, vulnerable households would be expected to shift production into more conservative, but less profitable, modes. Binswanger and Rosenzweig quantify this effect by considering the impact on profits of increasing the coefficient of variation of rainfall timing by one standard deviation. They find that for a household with median wealth levels, farm profits would be reduced by 15 percent, but for the bottom wealth quartile, income smoothing would reduce farm profits by 35 percent. On the other hand, they find that households in the top wealth quartile have adequate ways to cope with risk; as a result, increasing riskiness would have a negligible impact on the profitability of the richest farmers.

Pathway 2 describes consumption smoothing and includes all possible actions that can be taken in the event of transitory income shocks, so as to smooth disposable income and thereby smooth consumption, as well as possible, in current and future periods. If there are complete markets for savings, credit, and insurance services, then transitory income shocks that make disposable income deviate from ex-ante permanent income (that is, anticipated average income per period over the entire lifecycle) should be smoothed away by borrowing, saving, and insuring. Hence, transitory income shocks should not affect consumption patterns; consumption should therefore not track current income (Murdoch 1995). An increasing number of studies, discussed, for example, in Alderman and Paxson (1992) and Murdoch (1995) show, however, that households, in particular the poorer ones, are not able to adequately protect their consumption in the face of income shocks. Foster (1995) shows that when households confront severe events, such as the Bangladesh floods in 1988, the nutrition status of children in poorer households severely suffers as a result of insufficient informal coping mechanisms and access to credit. Similarly, in a study in Peru, Jacoby (1994) found that during adverse circumstances, credit constrained parents tended to withdraw children from school and put them into income-earning jobs, essentially substituting present consumption for future consumption. Moreover, Jacoby and Skoufias (1997) find that poorer small farm households in India, but not large ones, are inadequately insured ex ante; unanticipated income shocks significantly affect their children's school attendance. Jacoby and Skoufias (1997) conclude that child labor, and thereby school attendance, plays a significant role in the self-insurance strategy of poor rural households in India.

Improved access to microfinance may decrease the level of credit obtained at high costs from informal sources, and reduce the occurrence of distress sales of productive assets at low prices. Thus, a sell-off of productive assets (land, livestock, seeds) may be avoided. However, such a substitution of formal for informal credit will only occur if the formal credit and savings services are useful for the purpose of consumption smoothing. Loans that are approved only after considerable waiting time, that carry high transaction costs for loan application, or that are specifically given for production purposes and thereby tightly monitored are of limited use for consumption smoothing. In the same vain, savings deposits that can only be withdrawn after a longer waiting period or that are—as is common in the majority of credit-focused microfinance schemes—a fixed percentage of the loan amount and held as obligatory deposits until the loan is repaid, are of no use to those who wish to save for precautionary motives.

In the real-life presence of imperfect financial markets, households hold precautionary savings to self-insure as much as possible, so as to retain the capacity for future consumption smoothing. While the literature discusses precautionary savings that are held as monetary or physical capital, it is important to recognize that such savings can be in principal also held in the form of human and social capital. In the following, examples are given for each of the four forms of precautionary savings.

First, households may hold buffer stocks in the form of assets that can be liquidated in the event of transitory income shocks (Deaton 1992). Common physical and monetary assets used for precautionary savings in developing countries are money under the pillow, livestock, and food. These informal forms of savings are exposed to a number of risks, such as inflation, animal disease, and theft. Second, households, just like firms do, may choose not to utilize fully their available credit limits but to preserve the option to borrow for “worse” times. The credit limit is omitted in the conventional balance sheet of a firm or household, but nonetheless can be considered a specific form of monetary capital. Diagne, Zeller, and Sharma (1998) show that rural households in Malawi choose to maintain credit reserves for future periods. The households were found to be credit-constrained during the current period so that the holding of credit reserves came at the expense of current income for improving the household’s ability for smoothing future consumption. It was estimated that about half of each additional kwacha of formal credit line provided to the average household is borrowed at the margin; the other half is preserved for increasing future access to credit. However, Diagne, Zeller, and Sharma found for Bangladesh that households borrowed all of marginal increases in their formal credit limit. This unexpected result appears to be caused by the fact that the loan product of the NGO-supported group credit programs⁵ in Bangladesh did not allow the borrower to choose the amount of credit taken within the bounds of the credit limit. Subject to past loan repayment, increases in credit limit are a function of years of membership with the credit program, and the borrower is given

⁵ The NGOs included in the sample by Diagne, Zeller, and Sharma 1998 were the Association for Social Advancement (ASA), the Bangladesh Rural Advancement Committee (BRAC), and the Rangpur-Dinajpur-Rural Services (RDRS).

the choice to borrow all of that increase or drop out of the program. This finding also points out that quasi-automatic loan increases may not be optimal even in the case of credit-constrained households. Giving the choice to borrowers of how much to borrow within the bounds of their creditworthiness enables them to hold credit reserves for future consumption smoothing.

Third, precautionary savings can also be held in the form of human capital, for example by having more children so as to meet unexpected future shortages in household family labor. Fourth, and last, precautionary savings can be held in the form of social capital, for example by investing in personal relationships and membership in social and other institutions at the community level. That such social capital can have an impact on production and consumption has been shown by Grootaert (1998). It is not unreasonable to expect that social capital, just like any other form of capital, can be used more intensively in future periods when transitory income shocks occur. The culture of reciprocal gift giving is deeply embedded in many societies. Having more social capital can increase one's (insurance) claims toward society.

Because all four forms of precautionary savings enable households to hold reserves for future consumption smoothing, they can in principal act as substitutes. The degree of substitution is an empirical matter that is not well explored at all. Kazarosian's (1997) findings, derived from panel data for U.S. households, suggest that families save significantly less in monetary and physical capital if they have a larger number of children. Kazarosian explains that children can reduce income uncertainty during old age. This is a line of argument that is frequently voiced for the conditions in developing countries. That precautionary savings matter even for households relatively well covered by social security schemes and financial markets is shown by Carroll and Samwick (1998). They estimate for households in the U.S. Panel Study of Income Dynamics that about 45 percent of total net worth is held as precautionary savings. They further find that the bulk of precautionary savings is held in the form of rather illiquid assets. Only about a third of highly liquid assets are held for precautionary motives. Carroll and Samwick (1998) explain this result by noting that precautionary savings are also held to insure against relatively large income shocks, such as long spells of unemployment.

A number of policy implications for the roles of microfinance in income and consumption smoothing follow from this conceptual framework. When considering the first pathway in Figure 1 that affects ex-ante the income generation of households, two principal effects of access to financial services must be distinguished. The first is that—through the provision of credit and savings services—households can raise finance to enhance the level of the household's productive capital. With the provision of credit, the costs of (capital-intensive) technology and assets will be reduced relative to family labor. For example, instead of growing low-yielding local crop varieties with a low level of mineral fertilizer, access to credit may allow farmers to use more of improved seeds and fertilizer, thus producing a higher crop output per unit of labor and land (Feder, Just, and Zilberman 1985). Of course, savings services that enable the accumulation of assets serve the same purpose of providing capital for future investment and income generation. Generating extra income (or growth) is the traditional argument for the

provision of credit and savings services. Financial services that potentially raise the income of households are microenterprise credit, seasonal agricultural credit, medium- and long-term investment credit, and term deposits and savings accounts that earn interest income. This type of service is abbreviated as FI, that is, financial services for income generation. These services are fairly common among MFIs, and constitute most often the only type of financial services offered by microfinance institutions.

Credit, savings, and insurance services that address the demand for reducing ex-ante the variance of income or ex-post the variance of consumption are rarely offered by MFIs. Such services include insurance services against idiosyncratic or covariant production, consumption and market risks, the provision of savings services that are liquid and can be withdrawn at short notice, and the provision of consumption credit, or less controversially expressed, the provision of general household credit for maintaining family labor and the household's human and social capital. These services provide a shield against future risks and can thereby enable households to bear more risks. Since technology adoption and the level of production and investment increases with risk-bearing capacity (Eswaran and Kotwal 1985), the provision of financial services for consumption smoothing (FC) can have an indirect and positive effect on ex-ante income generation. Efficient FCs can further reduce the cost of the household for income and consumption smoothing, for example by substituting for some higher-cost informal savings, income diversification, personalized or group-based coinsurance strategies, as well as by substituting for some of the higher-cost informal sources of consumption credit.

FCs are particularly in demand in environments of considerable interannual and seasonal income fluctuations, and therefore, they are particularly relevant for rural households that depend mainly on agriculture for their livelihood. Moreover, FCs gain in relative importance over FIs for disadvantaged clientele groups, such as women, the poor, wage laborers, and those left out of any type of formal or informal social security system.

Based on this conceptual framework, it appears reasonable to expect that financial policies will do a better job in alleviating poverty and contributing to social protection when the financial services offered by MFIs seek to address not only the demand for FIs for income generation, but also the demand for FCs for income and consumption smoothing. Put in other words, policy may be well advised to recognize not only the potential contribution of microfinance to poverty alleviation through growth (that is enhancing income generation by the poor), but also the potential of microfinance for providing means of social protection that can complement other measures of public and informal safety nets.

3 Coping with Covariant and Idiosyncratic Risks through Microfinance Services

This section attempts to systematize the risks that poor households in developing countries face and that motivate the households' demand for financial services for income and consumption smoothing. This demand is contrasted with the type of services commonly supplied by microfinance institutions. The gap between current supply and demand by the poor defines areas for policy action as well as further research.

Tables 1, 2, and 3 list various categories of risks that affect the process of income generation of households or their consumption, respectively. These risks cause income to fluctuate and may create additional unexpected expenses that need to be met by ex-post consumption-smoothing types of measures. The second column in Tables 1 and 2 lists examples of typical informal responses to these risks, whereas the last column indicates the relevance of microfinance policy for addressing these risks.

When considering the risks listed in the tables, it is important to distinguish between idiosyncratic and covariant risks, that is, risks that affect only individuals or larger groups of people in the same locality, respectively. This is because the informal responses to risk, which are differentiated in the second column of the tables, are less effective in covering covariant risks than in protecting households against idiosyncratic risks. In general, informal responses are of a localized nature, mostly based on actions by individual household members or by informal institutions at the local community level to which the household members belong. Because of the dominance of personal and institutional responses only acting at the local level, the effectiveness of local responses to risk is lower. For example, Rosenzweig and Wolpin (1993) find that sales of bullocks in India are motivated by the need to smooth consumption. Yet, as demonstrated by Czukas, Fafchamps, and Udry (1995), the effectiveness of traditional forms of savings can be severely hampered by covariant risk, such as drought. Czukas, Fafchamps, and Udry explore the role of livestock as a form of precautionary savings in Burkina Faso. Their results show that livestock transactions play less of a role in consumption smoothing than is often assumed. This phenomenon suggests that drought as covariant risk can equally threaten the effectiveness of specific forms of precautionary savings held, in particular if poorly integrated markets for the assets lead to drastic declines in prices when a large number of households in a region seek to sell similar assets for consumption smoothing.

Table 1: Risks affecting income generation of household and its members

Risks related to ...	Examples of informal responses to risk	Relevance for micro-finance policy
Input markets (availability and quality of production inputs, including shortages of family labor due to ill health)	<p>Diversifying income sources (non-farm, on-farm, wage labor, temporary or permanent migration of household members).</p> <p>Establishing reliable input sources through formal contracts or through investment in social relations with input dealers.</p> <p>Entering bonded patron-client relationships by poor entrepreneurs with wealthy input suppliers (example tenant-landlord).</p> <p>Holding costly reserves for inputs (for example, seeds, raw material for microenterprise).</p> <p>Investing in social capital (informal groups that provide labor)</p>	<p>If input markets are not functioning well, credit for inputs (in cash) to micro-entrepreneurs may not create much benefit</p> <p>Organization of MFI clients to reap economies of scale, scope, and risk in purchasing inputs</p>
Production function (for example, covariant weather risks or idiosyncratic risks affecting business, crop, or livestock enterprise).	<p>Diversifying income (that is forgoing profits from specialization).</p> <p>Risk-reducing inputs (such as irrigation, pesticides, vaccination of animals).</p> <p>Postponing decisions (for example, sowing later).</p> <p>Diversifying operations spatially (for example, plot diversification).</p> <p>Choosing low-return enterprises that have lower risks</p>	<p>Credit and savings services for diversification in new enterprises.</p> <p>Provision of production insurance (crop, livestock insurance).</p>
Output markets (risks in finding a buyer and price risks).	<p>Diversifying income</p> <p>Establishing contracts/ informal relationships with output buyers (including bonded patron-client relationships with employers).</p> <p>Producing more for home consumption than for market (emphasizing autarky and forgoing gains from trade).</p>	<p>Addressing bottlenecks in marketing (again, lack of access to financial services may not be primary cause of income fluctuation).</p>

Table 1 systematizes the risks related to the generation of income by the household and its members in farm and non-farm microenterprises and by selling labor in the labor market. While the latter covers the risk of unemployment, the former are specific risks related to the availability of inputs (with respect to quantity, quality, and price risks), the stochastic production

function of the enterprise, and the availability of markets where products of the household and its enterprises can be sold. For brevity, the risks affecting income generation into idiosyncratic and covariant risks are not differentiated. It should be noted, however, that many of these risks are covariant. For example, risks related to the conduct and performance of input, output, and labor markets have similar effects on households that engage in the same enterprises. The less diversified the local economy in urban or rural communities, the larger the share of the population that is potentially affected by the same source of risk. In other words, the resilience and ability of informal networks to deal with these types of covariant risk factors diminish with a greater degree of specialization of the local economy. Negative effects on income are of course exacerbated by poorly integrated labor, financial, and commodity markets. The proper functioning of these markets often critically depends on infrastructure.

The third column in Table 1 highlights the potential role of microfinance policy to partially address these risks. When discussing the potential of microfinance, it is important at the outset to point out that the principle remedy for addressing these risks may not necessarily lie in improving financial markets, but in investing in road infrastructure, technology development and transfer, or in improving performance of commodity markets. To what extent microfinance matters will ultimately depend on the specific circumstances. With respect to risks occurring in the availability and quality of inputs, credit disbursed in cash may be of little use, and addressing the underlying bottlenecks and imperfections in input markets is likely to be more relevant in many circumstances. Yet, member-based financial institutions can exploit economies of scale, scope and risk by collective acquisition of inputs. The role of microfinance tends to increase when one considers risks related to the production function itself. Access to credit can help households to adopt risk-reducing inputs, such as investment in irrigation or adoption of disease-resistant crop varieties and pesticides, or to diversify risks by entering into new enterprises for which profits are weakly correlated with the traditional income portfolio of the household. For certain types of production risks that can be easily monitored and therefore insured, sustainable provision of insurance is possible. However, as far as farm enterprises are concerned, the provision of crop and livestock insurance is riddled with a number of difficulties that are hard to resolve in practice under the conditions of small-scale farming in developing countries. New information technology and satellite imaging that can decrease the cost of monitoring may however change the future prospects for sustainable insurance of risks in smallholder agriculture. However, at present, the role of financial sector policy in addressing these risks appears fairly limited. Last, with respect to risks related to output markets, reasoning similar to that for input markets holds. Insofar as access to finance can enable households to diversify their portfolio of enterprises to smooth income risks, microfinance could possibly make a contribution. However, for most circumstances, lack of road infrastructure, communication, and policy distortions in output markets are likely to play a greater role for volatility of household incomes related to this category of risks.

The discussion of risks related to income volatility points out the somewhat limited role of savings, credit, and insurance services related to income smoothing. The principal direct role that can be identified is that of savings and credit services, which enable households to acquire the necessary start-up capital for establishing new enterprises for which profits are weakly correlated with their existing portfolio. Moreover, access to credit and savings services can facilitate household's investment in risk-reducing assets such as irrigation or inputs such as pesticides. A relative advantage of credit and savings, compared with insurance, lies in the fact that credit and savings facilitates income smoothing (for example, by providing the capital for investing in irrigation) and ex-post consumption smoothing, as is discussed in more detail below. This double function of credit and savings cannot be performed by many specialized insurance products.

Access to financial services can have a far greater role for smoothing consumption, and thereby increasing the risk-bearing capacity of households for increasing future income. Two tables distinguish between rather infrequent but large risks that can wipe out the productive capacity of a household (Table 2), and risks that frequently occur and cause transitory shocks in consumption (Table 3).⁶

With respect to large, infrequent risks, such as war, political upheaval, major successive droughts, and other natural disasters (see the first row in Table 2), the household's ability to deal with such risks through informal responses is quite weak. This is either caused by the covariant nature of these risks (and the related weakness of informal responses to deal with such risks) or by the large impact of the risk on the household. For these covariant and large risks, the role of insurance and credit is fairly limited. Insofar as these sources of risk are covariant, the provision of sustainable insurance schemes appears quite impossible under the conditions in most low-income countries, unless the insurance company is well diversified at the national level and therefore can spread the risks over a large client base. In most cases, it is the state that is called upon to be the implicit insurer by providing social assistance, either through permanent income transfers to secure a minimum standard of living (in the case of permanent disability to earn a future income) or by giving temporary transfers to replenish productive assets of households and to treat workers' disability. Once the ability to earn an income is restored through private or public assistance, so that the capacity to repay a loan and to save is regained, subsequent access to savings and credit services can assist households in expanding the productive capital in successive periods.

⁶ Insofar as these risks concern the productive capacity of the household by affecting the ability of household members to work and generate income, these risks could also be viewed as affecting income generation and be listed under labor inputs in Table 1. However, here these lists are listed as ex-post shocks as they create additional potential demand for unanticipated consumption expenditures (such as the treatment of human diseases).

Towards Enhancing the Role of Microfinance for Safety Nets of the Poor

Table 2: Risks affecting consumption with chronic, permanent effects on the ability to earn an income

Risk related to ...	Informal responses to risk	Relevance for microfinance policy
Sliding into chronic poverty in its worst form (loss of all productive assets, including ability to work) often caused by covariant risks, such as natural disasters, war, political upheaval, and major economic crises, HIV/AIDS	Informal social welfare (for example, neighborhood help, giving to beggars, putting children in foster homes, remittances by extended family). Informal precautionary savings and investment in human capital (having children) and social capital (having access to networks that provide help).	No role for credit as there is no viable project to be financed and no repayment capacity. Provision of precautionary savings services. Other safety net measures are more relevant (public transfers to replenish assets, such as disaster relief or social security). Very limited role for insurance.
Permanent disability to work.	Same as above.	Disability insurance and precautionary savings services.
Old age or death of family member.	Informal precautionary savings (long-term investments in physical, human, and social capital that can provide income in old age).	Precautionary savings services Life insurance.

One may argue that temporary transfers by the state to replenish assets could be given on a loan instead of a grant basis. If the administrative network for properly administering such loans is in place and can be used at low transaction costs to the government and the target groups, choosing a loan over a grant system can be justified. Yet, if governments use—as is often done—local-level employees of certain line ministries who are inexperienced in the handling of credit, the repayment rates for disaster loans—droughts or flood, for example—are often extremely low. Low repayment rates, combined with additional administrative costs for loan provision and recovery, may well lead to total costs of service provision that are far higher for loans than for grants. Moreover, loosely monitored and ill-targeted disaster credit schemes by the state run the risk of destroying morale for repaying future loans.

For all three types of risks listed in Table 2, precautionary savings services can in principle play an important role. This is particularly true for cushioning against the risk of permanent disability and for the old age and death of family members. However, in the case of permanent disability, which is caused by idiosyncratic risks such as an accident, and certainly for old age, insurance services also have potential. For permanent disability and old age, in most cases there appears to be no role for credit simply because the risk under consideration wipes out

the capacity to earn an income and therefore repay the loan. However, if the disabled person possesses assets that provide a source of income (such as a house) or other good collateral, consumption credit can in principal be offered.

Table 3: Risks affecting consumption with usually transitory effects on the ability to earn an income

Risks related to ...	Examples of informal responses to risk	Relevance for microfinance policy
Health (temporarily affecting ability to work).	Reducing exposure to health risk, if causes are known. Holding precautionary savings.	Public health policy (including health insurance) is most relevant. Microfinance policy can complement by
1. Covariant health risks (such as malaria, flu).	Investing in social capital that provides labor, food, and care (but capacity of network for service provision may be weakened, too, because of covariance).	providing precautionary savings services with emphasis on low transaction costs for withdrawal and liquidity rather than return consumption credit.
2. Idiosyncratic health risks (such as many human diseases, accident, pregnancy)	As with covariant risks, but investment in social capital much more likely to be effective.	In addition to above, member-based MFIs can self-finance the demand for consumption credit out of internal savings or can retail specific insurance services.
Claims by social network to fulfil (financing social events, helping out friends and relatives in need).	Holding precautionary savings, as above.	Provision of liquid savings services for unexpected claims and term deposits for anticipated claims (such as marriage).
Divorce and other causes of household disintegration.	Maintaining ownership/control over assets brought into/ accumulated during marriage. Investing in social networks accessible by the individual household member.	Promoting savings accounts and credit lines for individuals, particularly women.

Table 3 lists risks that usually have transitory effects on the ability to earn an income. They therefore cause transitory shortfalls in consumption if informal responses are inadequate. A major source of risk for the poor is ill health, either caused by covariant diseases such as malaria and flu, or caused by many types of idiosyncratic diseases. The impact of health risks increase with the level of poverty because labor is the major production factor for the poor, while the rich may substitute own family labor by acquiring hired labor in case of temporary illness. Thus, it is often liquidity constraints that are the causes of shortfalls in income and consumption and in inadequate treatment of diseases. However, like imperfect commodity markets, if the public health system is not well functioning, so that proper medical care and medicine are not available, access to financial services may not do much good. It is therefore often more appropriate to invest in health infrastructure, in access to safe water and sanitation, that can improve these health risks. Only if this basic health infrastructure is in place and is accessible to the poor can access to financial services make a difference. In IFPRI's work, the short-run impact of access to financial services on nutrition was found to be insignificant in all case studies (Zeller and Sharma 1998). In the long run, however, access to financial services may increase household incomes and enable communal action to use part of that income to invest in health infrastructure, for example by funding a communal water borehole. If health services can be purchased locally, access to precautionary savings services and to credit are expected to have considerable potential in assisting the poor in dealing with transitory health risks. The role of financial services is equally important to finance consumption goods during illness.

Other sources of transitory risks causing volatility of the poor's consumption include the manifold claims that the social network can put on a household and its members, mostly the need to advance or reciprocate help to the extended family, friends, and neighbors and the requirements to finance social events for meeting cultural norms, such as marriage and burials. For these types of transitory events, the provision of precautionary savings appears most appropriate. Since these shocks can frequently occur, and some are hard to anticipate, a range of precautionary savings services that differ with respect to liquidity and return can be offered. For example, for marriage, long-term savings products, such as term deposits are more appropriate, whereas frequent and unanticipated claims by the social network could be dealt with through current accounts and highly liquid savings services.

The above discussion points to a number of specific risks, mostly related to consumption smoothing, that potentially can be addressed by MFIs. These risks are mainly of an idiosyncratic nature, and the dominant financial services that appear most feasible for MFIs to implement, as a response to these risks, are precautionary savings and credit. The poor's willingness to pay for financial services for income and consumption smoothing will of course depend on the effectiveness and costs of informal responses, including informal forms of precautionary savings, consumption, and insurance. Before exploring in the next section some innovations by MFIs, it should be emphasized that formal financial services responding to these safety net aspects of finance can crowd out informal responses, implying a smaller net benefit from formal services. If formal services are subsidized by the state, they can therefore create social costs that exceed

social benefits. Having said that, it should be noted that the evidence presented in second section showed that informal responses are far from adequate.

To find the right mix between publicly and privately provided safety nets is the true challenge. In a nutshell, some form of public assistance is necessary to alleviate poverty and protect the poor from major shocks. The main question is which policy, or which bundle of policies, addresses this problem in the most efficient manner. Moreover, informal responses are greatly weakened in their effectiveness if risks are correlated over time. They are less effective for those in the society who are vulnerable and socially excluded—those who lack sufficient access to informal self-help networks. Thus, informal responses are likely to provide an adequate cushion for some, but not for others, in particular the poor. Secular trends, such as the breakup of the extended family through migration and urbanization and demographic shifts, such as fertility decline and extended life expectancy, tend to reduce over time the efficiency of informal responses, particularly those for old age and for permanent disability. Because of this weakening of informal networks over time, the demand for publicly provided safety nets as well as the demand for financial services for consumption smoothing provided by MFIs are likely to increase over time in low-income countries.

4 Recent Innovations of Microfinance Institutions

This section concentrates mainly on idiosyncratic risks for which the immediate implementation potential of microfinance appears to be largest, and for which product innovations have already been introduced by MFIs.

Since most MFIs in developing countries at present are too small in terms of size of clientele and their geographical coverage, they are often unable to effectively cover covariant risks, either through direct insurance services or by pooling emergency funds financed by clients. However, as MFIs grow over time and reach operational scales like those achieved by Bank Rakyat Indonesia (BRI) or Grameen Bank, there is also considerable potential to address covariant risks sustainably. For example, the Grameen Bank and BRI both have rescheduled loans to clients in areas of natural disasters. BRI can do this without assistance by the state because of its high profits and its business conviction that losing a good borrower because of a covariant risk is also a loss to BRI. The Grameen Bank has also rescheduled loans in the past for clients affected by flood. Grameen Bank requires members to deposit small amounts of savings into a so-called emergency fund. The pooling of such funds over larger areas can in principal address covariant types of risks.

With respect to idiosyncratic risks that cause consumption to fluctuate, the major sources of risk are listed in Table 4 and summarized in the first column: (1) health risks, including pregnancy and temporary or permanent disability caused by accident or disease; (2) old age and death of family members (again, as long as death is not caused by covariant risks, such as war and AIDS); (3) claims by the social network or expenses for social events that need to be met by the household; and (4) the breakup of families because of divorce and other reasons that leave vulnerable household members at risk, particularly children, women, and the elderly. The second column of Table 4 describes innovations in financial products that specifically address these risks. The third column gives examples of MFIs that provide such services to their clients.

The provision of health insurance for low-income people in developing countries faces a number of challenges that are not discussed in this paper. In developed countries, and for formal-sector employees in developing countries, health insurance is usually provided by specialized large-scale private or public insurance institutions that are not part of the financial sector. Yet, MFIs can provide precautionary savings services and consumption credit to address these risks indirectly. Village banks that follow the FINCA model (Nelson et al. 1996) or the model developed by the French NGO Centre International de Développement et de Recherche (CIDR) (Chao-Beroff 1996) raise funds for internal on-lending to their members. The village bank model allows the members to decide on interest rates for savings deposits and for internal loans. For

example, the village banks supported by CIDR in Madagascar set savings rates between 24 and 36 percent per year, and on-lending rates at 36 to 48 percent per year, although the formal lending rate of the agricultural bank was only 14 percent. The lending rate set by the village banks is much higher than the one for loans from friends and relatives, but less than the lending rate of about 60 percent that socially distant money lenders charge on seasonal consumption loans (Zeller 1998). In many village banks, the members explicitly allowed for on-lending of funds for consumption purposes, and some village banks provide interest “subsidies” to members that need consumption loans. Other examples of MFIs that explicitly provide consumption credit include Caja Social in Mexico and BRAC in Bangladesh. BRAC members can borrow up to 75 percent of their savings deposit for emergency purposes. SEWA in India, which targets microloans to very poor women, allows their borrowers to stop loan repayment during pregnancy.

Health risks can also be addressed by the provision of precautionary savings services. This type of service is useful for all types of risk listed in Table 4 provided that the maturity of the deposit, its interest rate, and its transaction costs for depositing and withdrawing funds at short notice are adjusted accordingly. For health risks that occur relatively frequently and demand immediate response, the costs and time for withdrawal must be minimal. A current account at a village bank or a nearby bank branch offers such features, as does a term deposit that can be withdrawn at short notice with a penalty. In order to protect savings deposits, banking laws often hinder semiformal MFIs (such as village banks and group-based savings and credit schemes) to offer and to diversify their savings products in response to customer demands (Hannig and Wisniwski 1998). Yet, those MFIs that are registered under the banking or cooperative law often have a variety of savings products that respond to the demand for precautionary savings to cover risks of health, disability, social claims, or old age. Examples of banks that successfully offer savings services to a diverse clientele, including the urban and rural poor, are BancoSol in Bolivia and BRI in Indonesia.

Poor households accept negative returns on savings deposits, if costs and time of withdrawal of savings is minimal. Nonetheless, a diverse range of savings products that provide different forms of trade-offs between liquidity and return, is required to address the full range of savings needs of the poor. However, the optimal choice of savings products can be conditioned by the clients’ access to labor, food, and commodity markets. For example, if food markets during the hungry season are segmented and food prices are highly volatile, households may continue to save in the form of food, even if formal savings options with high liquidity and low transaction costs are accessible. Such conditions prevail in many remote rural areas with poor infrastructure. For example, in the rice market of Madagascar, regional price differences reach up to 300 percent and seasonal price differences, 100 percent (Minten et al. 1998). The imperfections in the food marketing system explain why the growth and performance of member-managed rice “banks” in Madagascar, linked with a cash credit program, have been quite successful during the 1990s. The rice bank scheme offers groups of smallholders the option to store their rice immediately after harvest when output prices are low and to take out cash loans

to finance consumption and to invest in off-farm enterprises during the dry season. The rice serves as collateral but is stored by the borrower themselves. Four to six months after the harvest when rice prices are high, the farmers sell their rice and repay their consumption loans. This credit cum in-kind savings scheme is very attractive to farmers who face volatile food markets because it allows households to more effectively smooth their consumption in the hungry season.

Another important type of risk for the poor is disability to work. In principle, precautionary savings can be used as an insurance substitute if insurance services are not offered to cover this risk directly. A rare innovation in this regard has been adopted by village banks in Kenya that are promoted by FINCA. The members of the village banks can purchase group disability insurance from a national insurance company. FINCA assists in retailing these services to the village banks.

A number of MFIs offer life insurance services to cover risks of death or lack of care during old age (see Table 4). Most often, however, the insurance contract only covers the outstanding debt of the borrower in case of his or her death. This is the case, for example, for BRI in Indonesia and ASA in Bangladesh. BRAC offers a life insurance contract to its poorest members, who are mostly women, paying out a predetermined sum in case the member dies.⁷ The insurance contract responds to two principal motives. First, in particular for women in rural Bangladesh, the death of the husband usually results in the woman's loss of access to all major assets of the household. The widow is then completely dependent on her children, her parents, or her father-in-law or brothers-in-law. By buying a life insurance policy and designating a beneficiary in her family, the woman can gain increased bargaining power to obtain care during old age. Second, women in single-parent households can provide some form of security to their children by buying life insurance.

Because of sociocultural constraints, women often cannot get a loan unless they are married and their husband is a cosigner on the loan application. MFIs ought to insist that such discrimination is not practiced for their savings and loan products. By providing women with individual credit lines and savings accounts, their bargaining power during marriage can increase (although this effect may not materialize, as discussed in Goetz and Sen Gupta 1996). Moreover, individual accounts for women will enable them to have a much stronger economic position in the case of the breakup of the family, due to divorce or the death of the husband.

⁷ When the author visited Bangladesh in 1995, a landless BRAC member showed him her insurance certificate. In case of her death, the contract would pay 5,000 taka (about US\$110) to her son. When asked about her motive for buying this insurance, she replied that the insurance gives her children more security in case she dies early and gives her more security during old age, when she will depend on her children.

5 Implications for Policy

Access to microfinance has the potential not only to assist the poor in earning income from microenterprises, but also to smooth their income and consumption. The first potential effect is the traditional argument for microfinance called the growth argument for microfinance. At present, it is the primary motivation for the microfinance movement. Yet, when targeting services to poorer groups, the second effect gains in importance. This is the safety net argument for public support of MFIs.

The conceptual framework presented in this paper seeks to distinguish between these two principal effects of and arguments for public support of MFIs. Following this framework, microfinance can address aspects of both growth and safety net policy. However, this paper focuses on the second aspect and discusses the types of risks that cause fluctuations in income as well as consumption. The largest potential for microfinance lies in its ability to address idiosyncratic risks, such as risks related to ill health, disability, old age, and divorce. When MFIs grow in scale and outreach to poor and non-poor groups, they also increase their potential to address covariant risks of their clientele.

A number of innovative MFIs offer financial products that respond to these risks. Most commonly found are precautionary savings services that provide clients with various products that offer choices between the transaction cost of withdrawal and the return earned on the deposit. Some MFIs offer lines of consumption credit. For example, some member-based financial institutions offer their members the flexibility to raise savings deposits for on-lending to members at terms freely decided by the members. Many village banks in Latin America and Sub-Saharan Africa sustainably offer consumption credit that is financed with internal savings collected from the banks' members. Some MFIs have ventured into insurance and have developed their own insurance products, mainly life insurance. Other experiences suggest that MFIs have a potential for retailing insurance products of the formal insurance sector to their clients.

The poor's willingness to pay for financial services for income and consumption smoothing will of course depend on the effectiveness and costs of informal responses, including informal forms of precautionary savings, consumption, and insurance. Therefore the provision of financial services may crowd out informal responses. To the extent that services by MFIs are indirectly subsidized by the state, for example by grants for product innovation, staff training, and by institutional expansion, formal financial services can create social costs that exceed social benefits. Yet it is fair to say that the informal responses are far from adequate and that publicly supported institutional innovation in microfinance can offer in many circumstances a viable policy instrument that generates net social benefits.

To find the right mix between publicly and privately provided safety nets therefore remains the true challenge. Under many conditions, MFIs can offer safety net types of services that are largely or exclusively financed by the clients. Alternative forms of safety net provision supported or directly implemented by the state, such as ex-post income transfers or public works, can carry high administrative costs for delivery and targeting and may require considerable response times after the shock has already occurred. In comparison, precautionary savings, insurance, and consumption credit are demand driven. And, by using local information, MFIs can adapt their services to specific demand patterns of various clientele groups. Depending on the subsidy level of the MFI, the costs of service provision can be financed largely or fully by the clients themselves. MFIs that are already established can offer financial products for income and consumption smoothing at relatively low variable costs, as the core business is already supported by growth-oriented financial services.

For these reasons, MFIs that want to increase their relevance for the poor are well advised to innovate with financial services for income and consumption smoothing. Public action can further promote innovations by supporting pilot projects and related action research. Evaluations of MFIs that receive support from the government or donors in order to make a contribution to the alleviation of poverty ought to include checks on whether the MFI provides financial products for income and consumption smoothing, such as precautionary savings services, emergency credit, insurance services, or implicit insurance substitutes. Such checks can be undertaken rapidly and at low cost by simply looking at the terms of the financial products currently offered, and they can identify other poverty-oriented product innovations that can be easily be implemented and can in many circumstances increase the business volume and profitability of the MFI.
